# All-Pairs Shortest Path

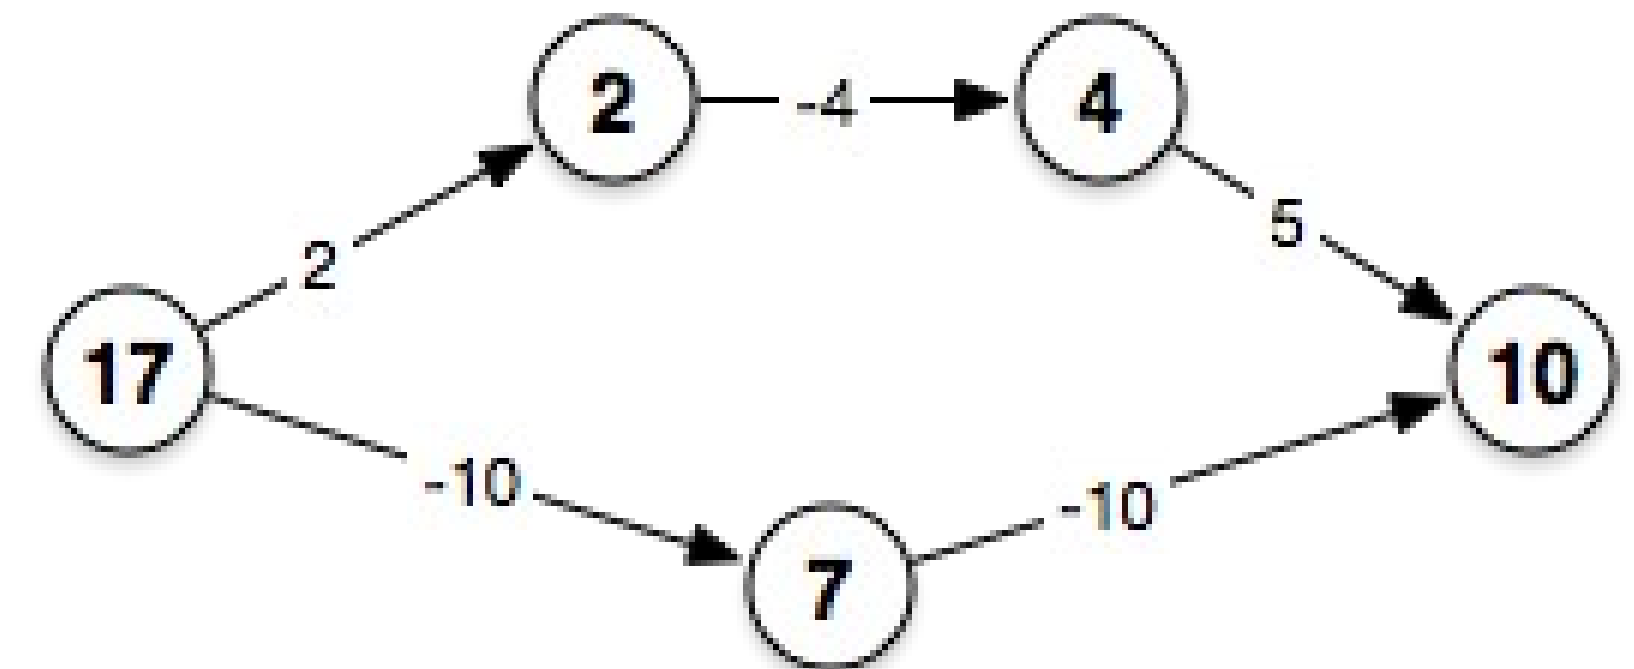

- Input: Directed Graph
- Output: Shortest distances between all possible source-destination pair vertices
- Reduce the problem to  $n$  dijkstra's
  - $O(n \cdot m \log n)$ 
    - If  $G$  is sparse:  $O(n^2 \log n)$
    - If  $G$  is dense:  $O(n^3 \log n)$
  - What about negative edges?

# Possible solutions

- For negative edges reduce the problem to  $n$ -Bellman-Ford
  - $O(n \cdot m \cdot n)$ 
    - If  $G$  is sparse:  $O(n^3)$
    - If  $G$  is dense:  $O(n^4)$
- Can we do better?

# Floyd-Warshall Algorithm

- Principle of optimality
  - Key point: order the vertices  $V = \{1, 2, \dots, n\}$  (similar to Knapsack)
- Notation
  - $V^k = \{1, 2, \dots, k\}$
- Suppose  $G$  has no negative cycle
  - Fix a source,  $i \in V$ ,
  - Fix a destination,  $j \in V$ ,
  - Fix a value,  $k \in \{1, 2, \dots, n\}$
- Let  $P =$  shortest  $i$ — $j$  path with internal nodes in  $V^k$

# Principle of optimality

- Case 1: if  $k$  is not internal to  $P$ 
  - $P$  is the shortest cycle free  $i$ — $j$  path using  $V^{k-1}$
- Case 2: if  $k$  is internal to  $P$ 
  - $P_1 =$  shortest  $i \rightarrow k$  path, with  $V_{k-1}$
  - $P_2 =$  shortest  $k \rightarrow j$  path, with  $V_{k-1}$

# Recurrence

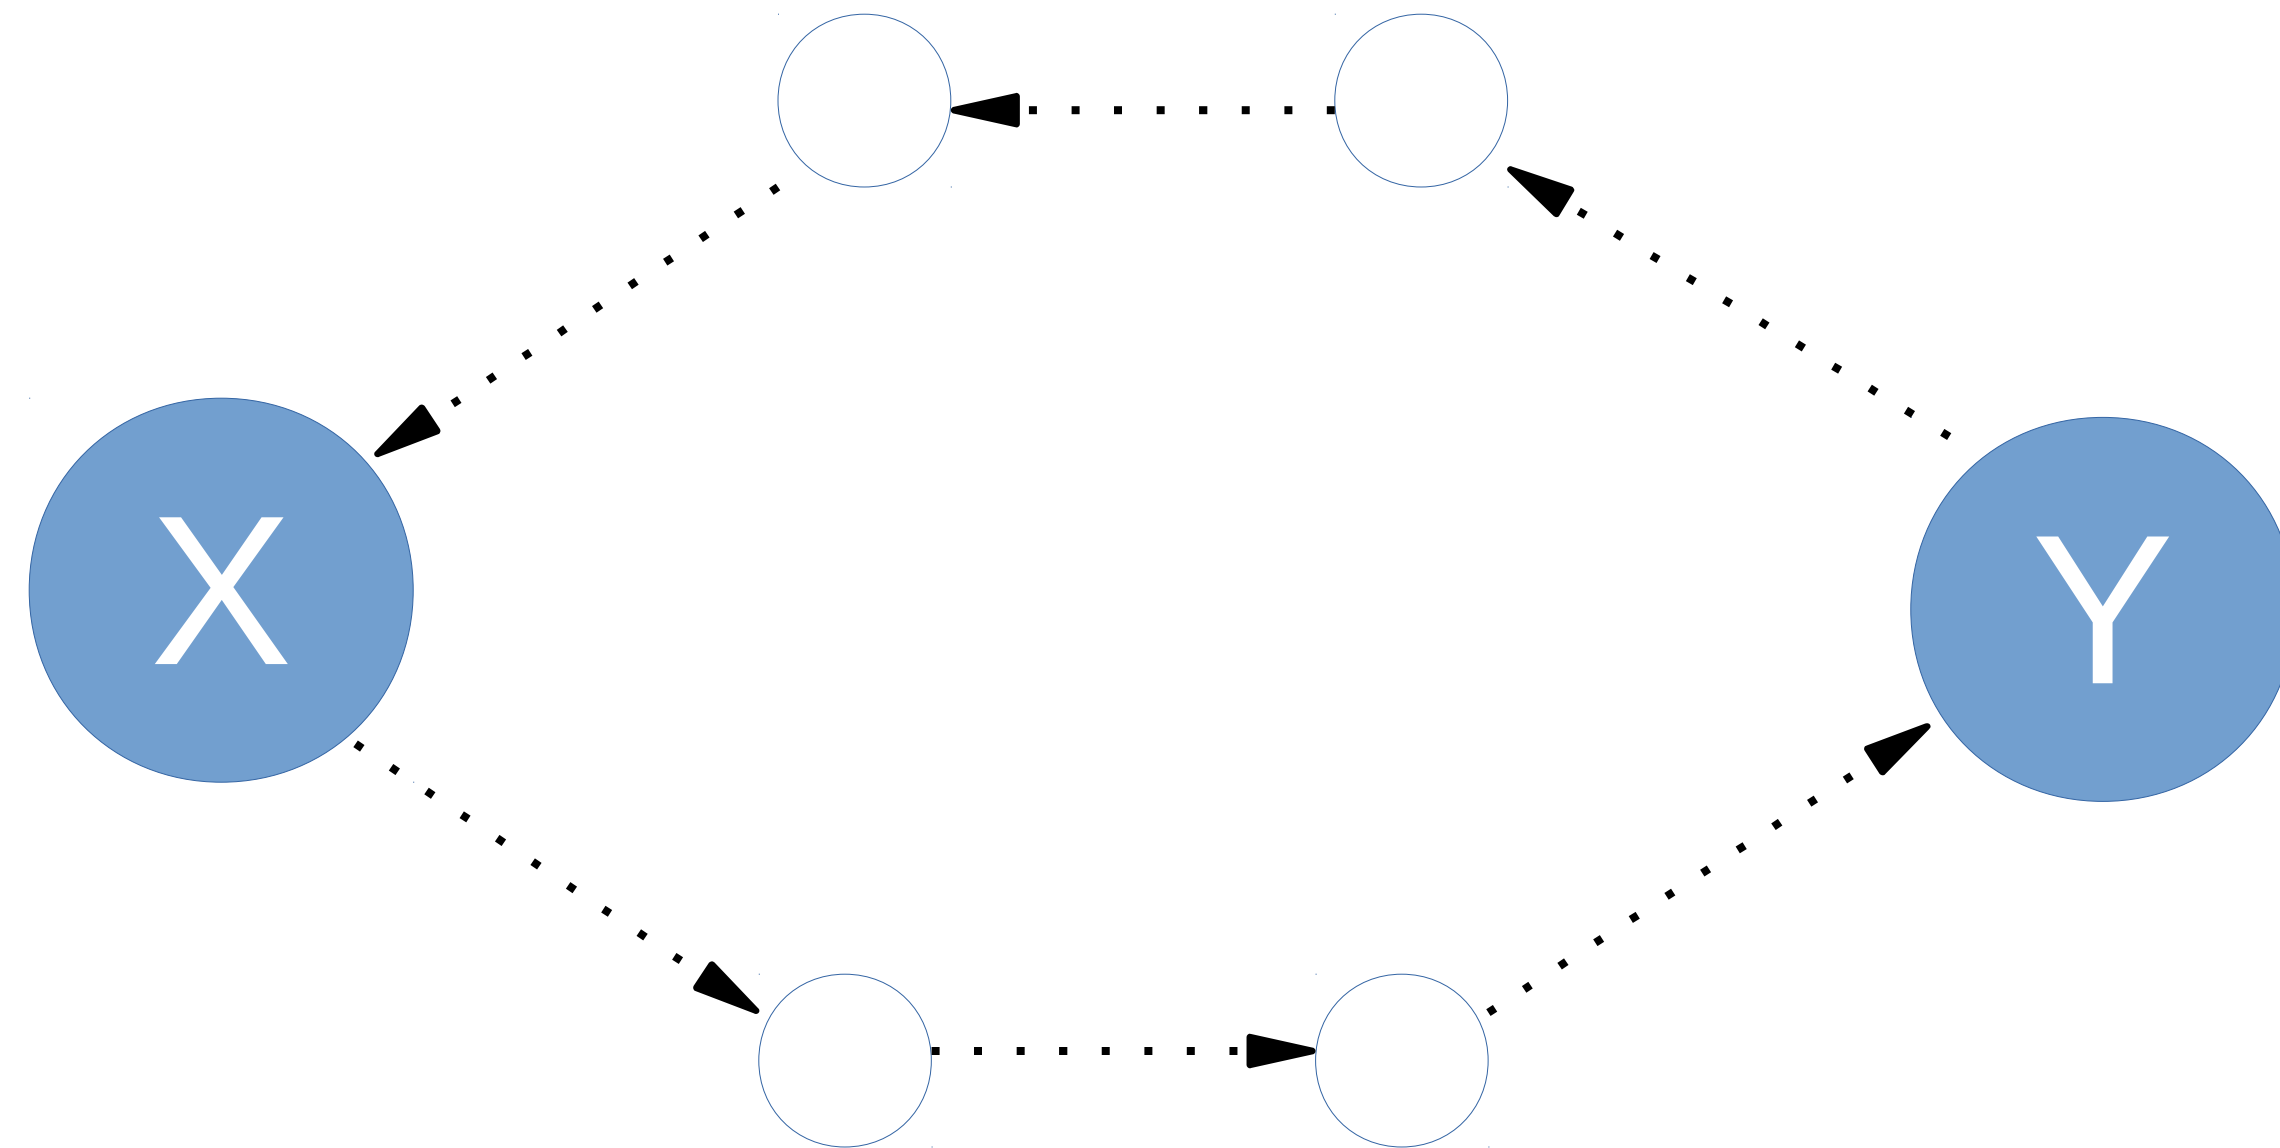

- $A_{i,j,k}$  = length of the shortest  $i \rightarrow j$  path with internal node  $V^k$
- $A_{i,j,k} = \min \{ A_{i,j,k-1} , A_{i,k,k-1} + A_{k,j,k-1} \}$
- For all possible values of  $i,j,k$

# Algorithm

1.  $A = \text{3d-Array } (i, j, k)$
2.  $A[i, j, 0] = \text{if } (i == j) \rightarrow 0$
3.        $\text{if } (i, j) \in E \rightarrow \text{Length}[i, j]$
4.        $\text{else} \rightarrow \infty$
5.  $\text{for } k = 1 \text{ to } n:$
6.      $\text{for } i = 1 \text{ to } n:$
7.        $\text{for } j = 1 \text{ to } n:$
8.          $A[i, j, k] = \min( A[i, j, k-1],$
9.                $A[i, k, k-1] + A[k, j, k-1] )$

# Negative cycle?

- If  $A[i,i,n] < 0$  for at least one  $i \in V$  then there must be a negative cycle.
- When calculating  $A[i,i,n]$ , the second case must've produced a negative value.

# Reconstruction?

- We need to keep track how many vertices we used to generate the shortest path in order to back track.
- $B[i,j]$  = max label of an internal node on a shortest  $i - j$  path.

```
1.  A = 3d-Array (i, j, k)
2.  B = 2d-Array
3.  A[i,j,0] = if (i == j) → 0
4.              if (i,j) ∈ E → Length[i,j]
5.              else → ∞
6.  for k = 1 to n:
7.      for i = 1 to n:
8.          for j = 1 to n:
9.              case1 = A[i,j,k-1]
10.             case2 = A[i,k,k-1] + A[k,j,k-1]
11.             if (case1 < case2):
12.                 A[i,j,k] = case1
13.             else:
14.                 A[i,j,k] = case2
15.                 B[i,j] = k
```

# APSP Comparison

	Sparse	Dense	Note
<b>n•Dijkstra's</b>	$O(n^2 \log n)$	$O(n^3 \log n)$	Non-negative edges
<b>n•Bellman-Ford</b>	$O(n^3)$	$O(n^4)$	Negative Edges
<b>Floyd-Warshall</b>	$O(n^3)$	$O(n^3)$	Negative Edges

# Johnson's Algorithm

- We just want to Dijkstra's because it's so fast. But we have to deal with negative edges.
- Can we get rid of them?
- Idea 1: shift the value to eliminate the negatives.
  - It works if two paths have same # of edges

# Getting Rid of negative edges

- Idea 2:
  - Fix a  $P_v$  for each  $v \in V$ .
  - For every  $e = (u,v)$  of  $G$ ,
$$c'_e = c_e + P_u + P_v$$
  - Given a path,  $P: s \rightarrow t$ ,  $L = \sum c_e$
  - Note,  $\sum c'_e = \sum c_e + P_u + P_v$
  - Then  $L' = L + P_s - P_t$
  - This preserves shortest path!
- Only if we can find  $\{P_v\}$  that will make every path length non-negative...

# Johnson's Algorithm

- Algorithm Reduction
  - 1 invocation of Bellman-Ford to get rid of negative edges –  $O(mn)$
  - $n$  invocation of Dijkstra to find all shortest paths –  $O(n m \log n)$
- Bellman-Ford to rid of negative edges:
  - Add a starting vertex  $S$  and create  $n$  edges between  $S$  and all other vertices with edge length of 0.
  - Call Bellman-Ford to find the shortest paths using  $S$  as the source.
  - $P_v$  = length of the shortest path from Bellman-Ford
- But does it work?

# Proof

- Claim: for every edge  $e \in G$ ,  $c'_e = c_e + P_u + P_v$  is non-negative

- Proof:

- Fix an edge  $(u,v)$

- $P_u =$  length of shortest path  $S \rightarrow u$

- $P_v =$  length of shortest path  $S \rightarrow v$

- Let  $P =$  a shortest  $S \rightarrow u$  path in  $G'$

- $P + (u,v) = S \rightarrow v$  path with length  $P_u + c_{u \rightarrow v}$

- $P_v \leq P_u + c_{u \rightarrow v}$

- $c'_{u \rightarrow v} = c_{u \rightarrow v} + P_u - P_v \geq 0$

# Johnson's Algorithm

- 1)  $G' = \{S + V, n \text{ edges with } 0 \text{ length from } S \text{ to } v + E\}$   $O(n)$
- 2) Run Bellman-Ford on  $G'$  with  $S$  as source, if negative cycle is detected then halt  $O(mn)$
- 3) For each  $v \in G$ ,  $P_v = \text{length of shortest path } S \rightarrow v \text{ in } G'$ , and for all  $e \in G$ , calculate the new length:  $c'_e = c_e + P_u - P_v$   $O(m)$
- 4) For each vertex  $u$  of  $G$ , run Dijkstra in  $G$  with  $\{c'_e\}$  using  $u$  as source:  $d'(u,v)$   $O(n \cdot m \log n)$
- 5) For each pair of  $u, v \in G$ ,  $d(u,v) = d'(u,v) - P_u + P_v$   $O(n^2)$
